

Galileo
Ferraris

Galileo Ferraris' Contest preliminary results

April 11, 2024

Galileo
Ferraris

- the first part of the workflow (steps 1 \rightarrow 4) is fully operative
- thermal and structural modules are now under testing to hone their accuracy
- first datasets on electromagnetic problem have been generated on one motor size (approx. `Tesla model 3`) and the *reliability* of results has been assessed
- a share of the results KPIs are currently been used to train the *surrogate*:
 - torque
 - torque ripple
 - copper volume
 - permanent magnet volume

first two KPIs are related to motor performance, the remaining two to its cost-effectiveness

Galileo
Ferraris

- a dataset containing about 5000 records has been created sampling a 8 dimensional degrees of freedom space
- CPU time needed to create the dataset on a HPC cluster is of about 12 *hours*
- *surrogate* models based on different approaches (statistical, support vector machines, neural networks) have been applied

Surrogate modelling (preliminary)
